Below is a smaller version of the data from a future lab called flights_mini. It contains all flights out of Oakland (OAK) from December 2020. This data frame is used to create the plot that follows. distance refers to the distance a given plane travels on its flight, measured in miles. carrier refers to the carrier code for a specific airline.

- 1. Which of the following interpretations of the plot above are true? (select all that apply)
- (A) The carrier with the most heavily skewed distance distribution is HA.
- (B) The median distance of the flights operated by DL, G4, and OO are roughly equivalent.
- (C) The minimum distance traveled in this data set is roughly 200.
- (D) The carrier with the greatest variability in distance, as measured by the IQR, is AS.

Consider the small data set from the notes.

$$6 \quad 7 \quad 7 \quad 7 \quad 8 \quad 8 \quad 9 \quad 9 \quad 10 \quad 11 \quad 11$$

2. The data set above was measured in meters, but what would have happened if it had been measured in decimeters (10 decimeters to a meter)? Provide reasoning for would happen to the measures of center - mean, median, mode - if it had instead been measured in decimeters. Repeat the exercise for three measures of spread: range, standard deviation, and IQR. Which measures remain the same after a multiplicative change in units?

- 3. Sketch your best sense of the distribution of the following variable(s). For each, please:
 - i. Use a form of statistical graphic that emphasizes the important elements of the distribution.
- ii. Label the axes and provide plausible values for the tick marks.
- iii. Describe in words the shape of the distribution.
- iv. State which measure of center and spread would be most appropriate and approximate their values.

Make a note of any assumptions you're making in interpreting these variable names.
